It is in a single of the best book. This is for those who statte there had not been a well worth reading through. Once you begin to read the book, it is extremely difficult to leave it before concluding.

Not illustrated. 1911 Excerpt: .of a measurement a unit in length, R the probable error of the total observed length, and l that observed length. Then (26) reduces to (37) $R = r\sqrt{l}$ that is, the probable error of a measurement of a line increases with the square root of its length. For example, the value of r for measurements with an engineer's tape on smooth ground is about 0.005: hence, for a line 100 feet long, R is 0.05 feet, and for a line 1,000 feet long, R is 0.16 feet. Since, by (18), weights are inversely as the squares of probable errors, and, by (37), the squares of probable errors are directly as the lengths of lines, it follows that the weights of linear measurements are inversely as their lengths, or (38) $w \propto 1/l$. Hence, if the weight of a measurement of a unit's length be w , the weight of a measurement of the length l will be w/l . This principle is to be used in combining linear measurements for which the value of r is the same. 92. The value of r may be found by measuring a line of the length l many times, and computing R by the methods of the last chapter. Then, by (37), the value of r is known. For instance, take the eight measurements of a line about 189 meters long, which are discussed in Art. 84, for which the probable error of a single observation was...
